

## Blueclaw's Technical Test

The aim of this test is to product a system capable of loading, modifying and saving some data using PHP, HTML and JavaScript. You should use best-practices where appropriate, ensuring that you have separate your presentation and logic.

1. Modify the given "index.php" file to submit the info to "save.php".
2. Make a file "save.php" to write the submitted data into a PHP-serialized string, and save it to a file on the server. Use a model class to do this, with "save" and "load" methods.
3. Create a new class by extending your model class, and make the new class able to represent an additional "job\_title".
4. Modify index.php so that it reads the data from "data.ser" via the extended model, and displays it in the webpage.
5. Modify "index.php" and "save.php" to also allow the person's job title to be saved and edited.
